²ВНИИА им. Н. Л. Духова, Росатом

Сообщение на совещании «Исследования в области физики высоких плотностей энергии лазерными и электрофизическими методами» 2-го апреля 2018 г.

Focusing conditions:

- Fluence absorbed from ~ 0.01 to $\sim 1 \text{ J/cm}^2$
- radius of focal spot R_L :
- $R_L \gg \lambda$
- $R_L \sim \lambda$
- beam structure :
- $F=\max$ in center
- $F=0$ in center

Laser-matter interaction

- Targets: bulk targets, film targets
- Thin films – thick films
 - Free standing films, supported films
 - Laminates
 - Nanoparticles formation
 - Powders, sintering

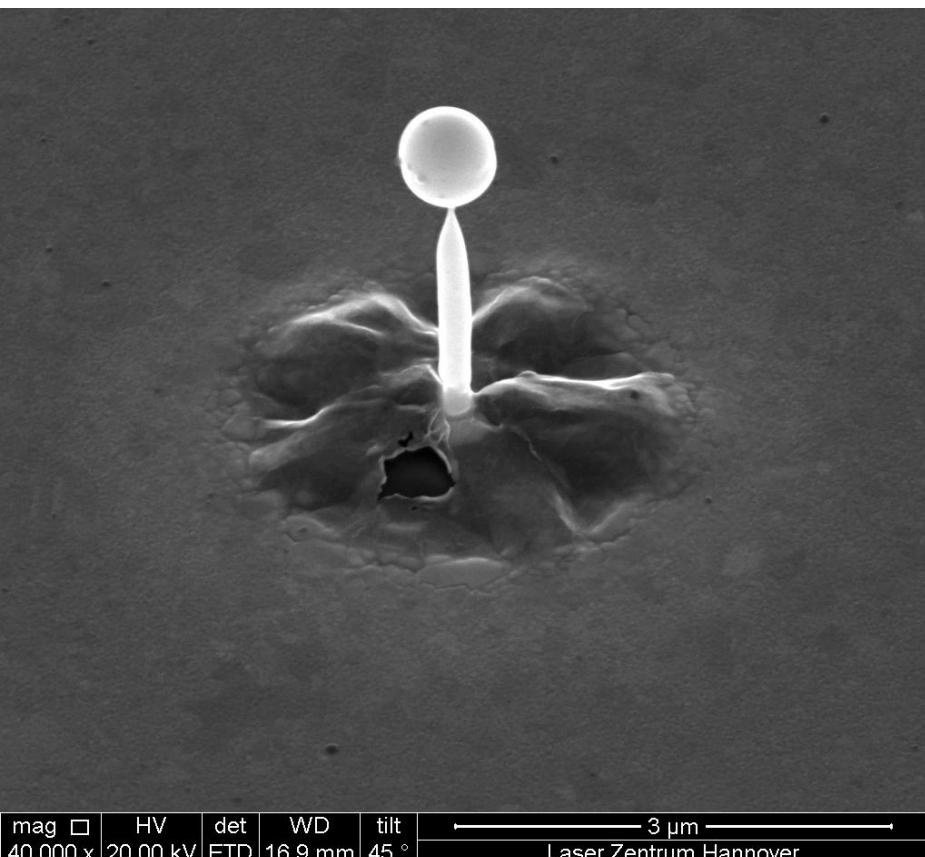

Short pulses 1 ps and less. Film is **thin** if HAZ is thinner than d_f – film thickness
Thickness of HAZ d_T is from 10s to 100s nm in metals

Thick films are if d_f is 2-5 times thicker than HAZ

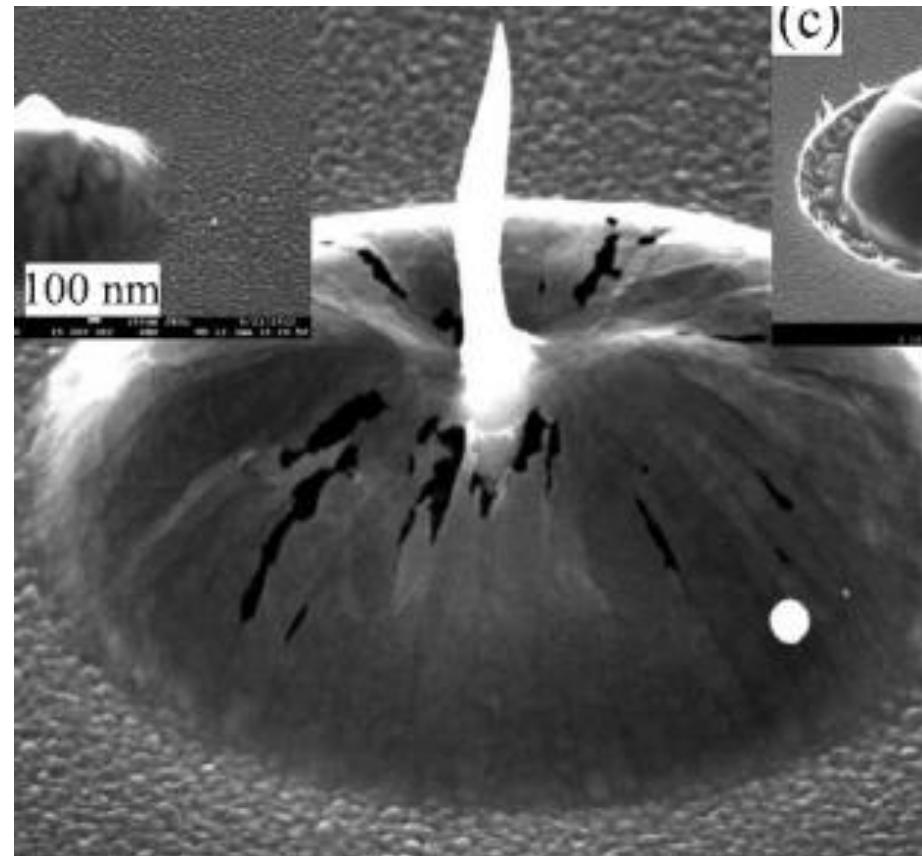

Bulk targets if film is 7-10 times and more thicker than HAZ

Blistering of thin films + tight focusing

tight focusing is diffraction limited focusing
then for IR-UV light a radius of focal spot is $\sim 1 \mu\text{m}$

Физика воздействия лазера на металл

$$\rho(z^o, t) \frac{\partial z(z^o, t)}{\partial z^o} = \rho^o, \quad \frac{\partial z(z^o, t)}{\partial t} = u(z^o, t),$$

$$\rho^o \frac{\partial u}{\partial t} = \frac{\partial P(z^o, t)}{\partial z^o}, \quad P = P_i + P_e,$$

$$\rho^o \left(\frac{E_e}{\rho} \right)_t = -q' - \frac{\rho^o}{\rho} \alpha (T_e - T_i) + \frac{\rho^o}{\rho} Q - P_e \frac{\partial u}{\partial z^o},$$

$$\rho^o \frac{\partial (E_i/\rho)}{\partial t} = \frac{\rho^o}{\rho} \alpha (T_e - T_i) - P_i \frac{\partial u}{\partial z^o},$$

Физика воздействия лазера на металл

$$\rho(z^o, t) \frac{\partial z(z^o, t)}{\partial z^o} = \rho^o, \quad \frac{\partial z(z^o, t)}{\partial t} = u(z^o, t),$$

$$\rho^o \frac{\partial u}{\partial t} = \frac{\partial P(z^o, t)}{\partial z^o}, \quad P = P_i + P_e,$$

$$\rho^o \left(\frac{E_e}{\rho} \right)_t = -q' - \frac{\rho^o}{\rho} \alpha (T_e - T_i) + \frac{\rho^o}{\rho} Q - P_e \frac{\partial u}{\partial z^o},$$

$$\rho^o \frac{\partial (E_i/\rho)}{\partial t} = \frac{\rho^o}{\rho} \alpha (T_e - T_i) - P_i \frac{\partial u}{\partial z^o},$$

Уравнение термодинамического состояния с учетом двух-температурных состояний

Физика воздействия лазера на металл

$$\rho(z^o, t) \frac{\partial z(z^o, t)}{\partial z^o} = \rho^o, \quad \frac{\partial z(z^o, t)}{\partial t} = u(z^o, t),$$

$$\rho^o \frac{\partial u}{\partial t} = \frac{\partial P(z^o, t)}{\partial z^o}, \quad P = P_i + P_e,$$

$$\rho^o \left(\frac{E_e}{\rho} \right)_t = -q' - \boxed{\frac{\rho^o}{\rho} \alpha (T_e - T_i)} + \frac{\rho^o}{\rho} Q - P_e \frac{\partial u}{\partial z^o},$$

$$\rho^o \frac{\partial (E_i/\rho)}{\partial t} = \frac{\rho^o}{\rho} \alpha (T_e - T_i) - P_i \frac{\partial u}{\partial z^o},$$

Электрон-ионный обмен энергией

Физика воздействия лазера на металл

$$\rho(z^o, t) \frac{\partial z(z^o, t)}{\partial z^o} = \rho^o, \quad \frac{\partial z(z^o, t)}{\partial t} = u(z^o, t),$$

$$\rho^o \frac{\partial u}{\partial t} = \frac{\partial P(z^o, t)}{\partial z^o}, \quad P = P_i + P_e,$$

$$\rho^o \left(\frac{E_e}{\rho} \right)_t = -q' - \frac{\rho^o}{\rho} \alpha (T_e - T_i) + \frac{\rho^o}{\rho} Q - P_e \frac{\partial u}{\partial z^o},$$

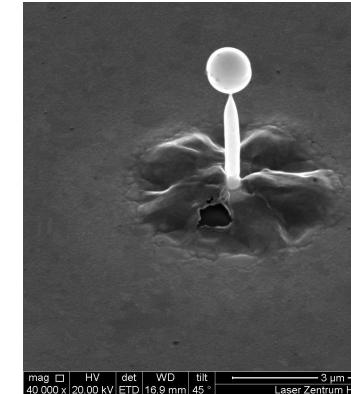

$$\rho^o \frac{\partial (E_i/\rho)}{\partial t} = \frac{\rho^o}{\rho} \alpha (T_e - T_i) - P_i \frac{\partial u}{\partial z^o},$$

Электронная теплопроводность
с учетом двух-температурных состояний

$$q = - \frac{\rho \kappa}{\rho^o} \frac{\partial T_e}{\partial z^o}$$

Преодоление разрыва между наличными на сегодня ресурсами и требуемыми

- $3000*3000*(50+3*50)*60 = 10^{11}$ атомов
- $(0.1-1)*10^9 = \text{limit}$
- Как обойти?
- 1) разделить на начальную стадию $\sim df/cs$ и последующую RL/Vf
- 2) начальную стадию описать с помощью 2Т-ГД кода (двухтемпературный гидрокод) \rightarrow тогда мы знаем Vf в эксперименте
- 3) полет пленки после ее отрыва от подложки моделировать посредством МД

Преодоление разрыва между наличными на сегодня ресурсами и требуемыми

- $3000*3000*(50+3*50)*60 = 10^{11}$ атомов
- $(0.1-1)*10^9 = \text{limit}$
- Как обойти?
- 4) МД-МК код. МК=Монте-Карло = вариация коэффициента теплопроводности каппа
- 5) МД полет. Использование теории подобия V_f это скорость пленки, она же $V_c(t=0)$

$$v_\sigma = 2\sqrt{\sigma/(\rho d_f)} = 46 [\sigma/(1000 \text{dyne/cm})]^{1/2} [\rho/(19.3 \text{g/cm}^3)]^{-1/2} [d_f/(100 \text{nm})]^{-1/2} [\text{m/s}]$$

$$v_\chi = \chi/R_L = 100 [\chi/(1 \text{cm}^2/\text{s})] / [R_L/(1 \mu\text{m})] [\text{m/s}], \quad v_{0\chi} = v_c(t=0)/v_\chi.$$

Преодоление разрыва между наличными на сегодня ресурсами и требуемыми

- 2Т-ГД код \rightarrow тогда мы знаем Vf в эксперименте

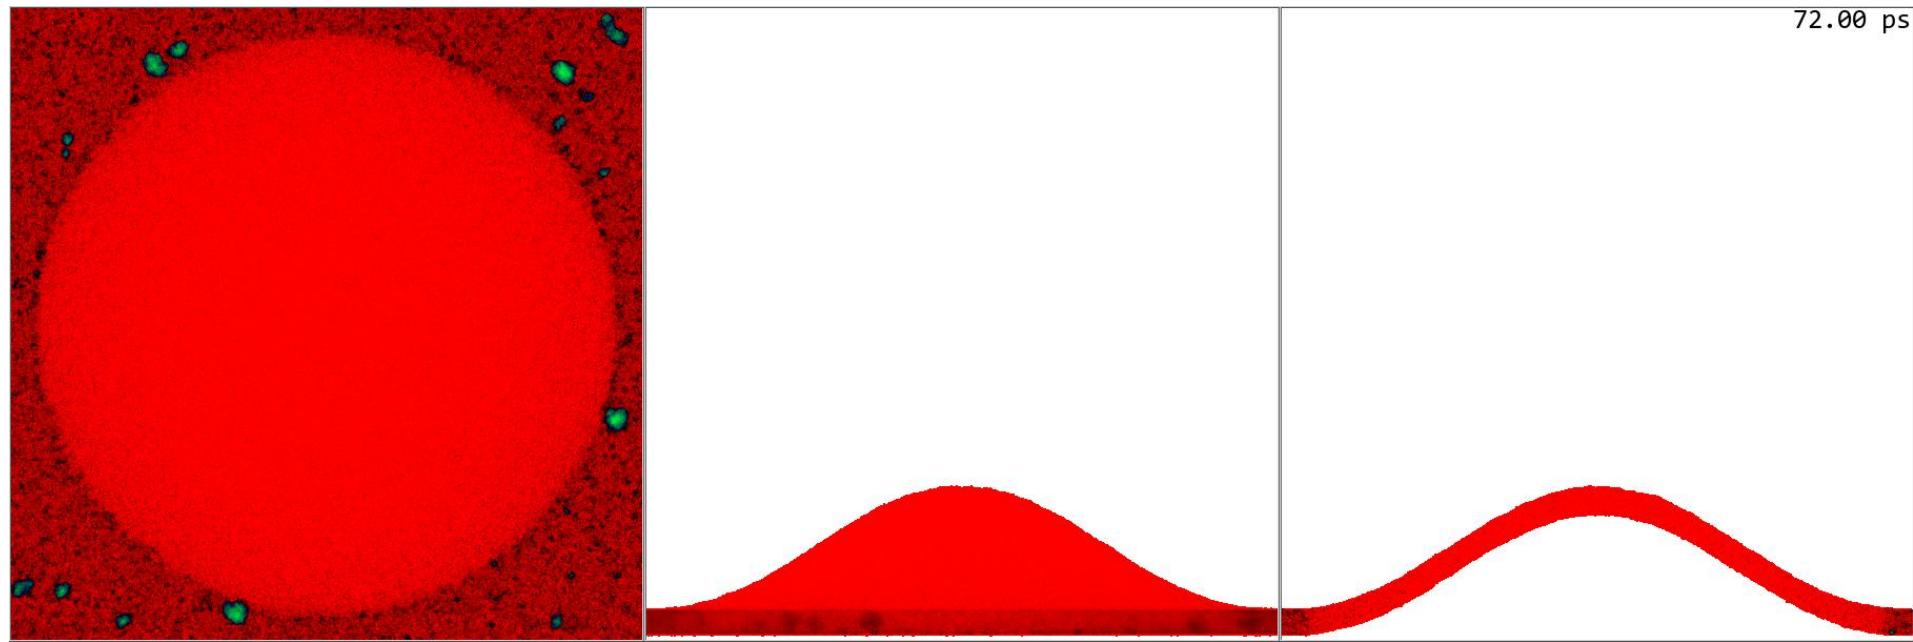

$$v_\sigma = 2\sqrt{\sigma/(\rho d_f)} = 46 \left[\sigma/(1000 \text{dyne/cm})\right]^{1/2} \left[\rho/(19.3 \text{g/cm}^3)\right]^{-1/2} \left[d_f/(100 \text{nm})\right]^{-1/2} [\text{m/s}]$$

$$v_\chi = \chi/R_L = 100 \left[\chi/(1 \text{cm}^2/\text{s})\right] / [R_L/(1 \mu\text{m})] [\text{m/s}], \quad v_{0\chi} = v_c(t=0)/v_\chi.$$

- Получили экспериментальные значения Vf/Vsigma, Vf/Vchi : капиллярное число и тепловое число
- df в МД на порядок меньше \rightarrow Vsigma и Vf в МД в $\sqrt{10}$ раз больше
- RL в МД в 5 раз меньше. Уменьшаем chi так, чтобы тепловое число Vf/Vchi было как в опыте

Large scale MD: few 100s mln atoms

MD = Molecular Dynamics. The code includes Monte-Carlo heat transfer, thus it describes cooling and thus it describes freezing = re-solidification !
Solid is shown by green colors, while molten gold by red colors

EHT = 5.00 kV

Свободновисяющие пленки

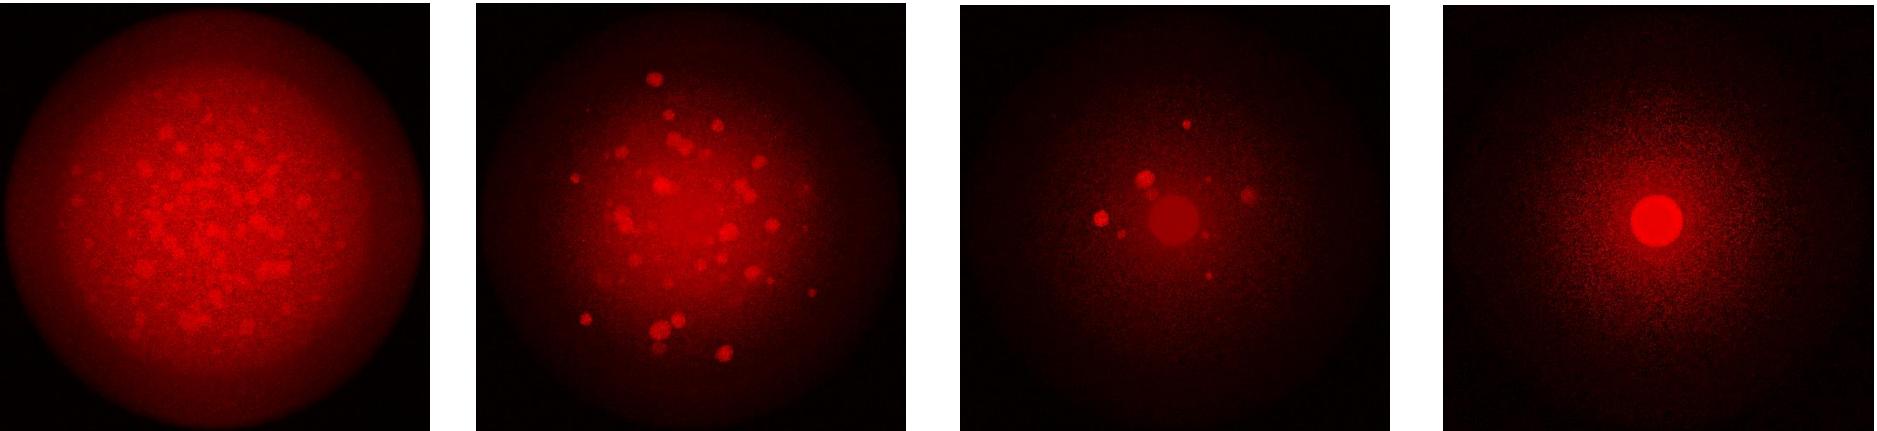

The free-standing case. Red=liquid, green=solid

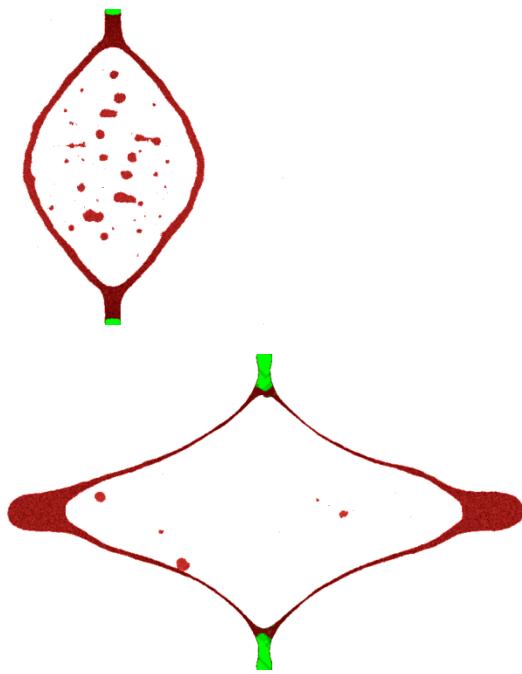

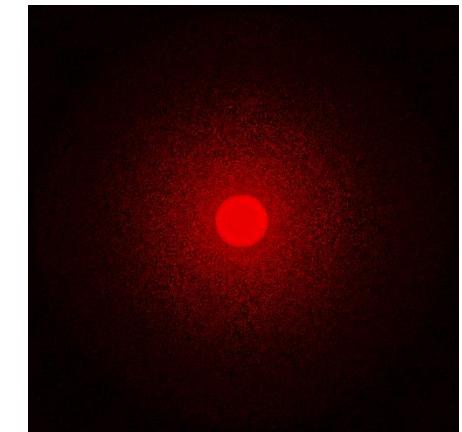

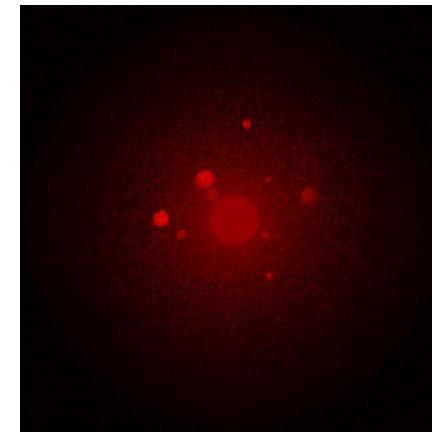

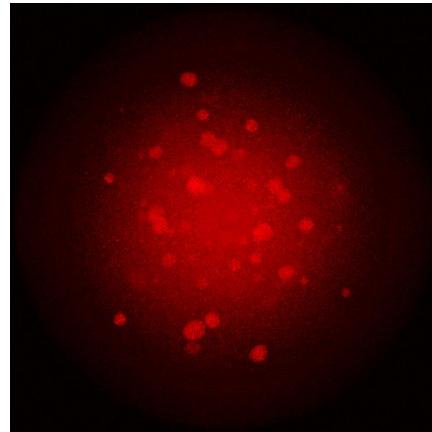

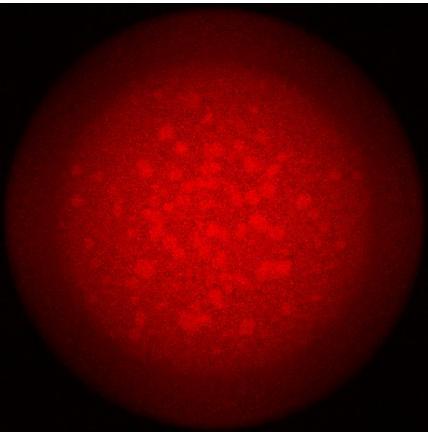

- Shell (two of them) forms from free-standing film
- The shell survive in spite of hard bombardment by fragments of foam decomposition
- Capillarity stops and return back the shell, but it cannot stop the jet formed thanks to Rayleigh-Taylor type of jetting. Solidification freezes liquid. Rayleigh-Plateau separation of droplets

The free-standing case

- In the previous page the side view onto breaking free-standing shell was shown
- We saw a struggle between inertia v. capillarity
- We saw how freezing stops moving liquid in its motion
- Here the view from above is given.
- This is temperature field: more red are hotter. The bright spots are droplets bombarding the shell from inside

The free-standing case

At the left side: Scheme of fs-laser action through water on gold. Intensities are below optical breakdown of water. At the right: Instant profiles of density (blue curve) and pressure (orange curve) at $t = 20$ ps after fs-laser action. The label 2 shows instant position of shock in water, 3 is a layer of shock compressed water, 1 is the contact between water and Au. The layer between the digits 1 and 5 is the ATMOSPHERE 4 made from Au. It is formed as a result of deceleration of the unloading Au by water. The molten Au continues up to the depth $x=180$ nm. Fluctuating region on the density profile to the right side relative to the label 5 ($x \sim 0$) presents the layer where nucleation and development of two-phase liquid-vapor Au continue.

2T-HD 1D simulation results -2

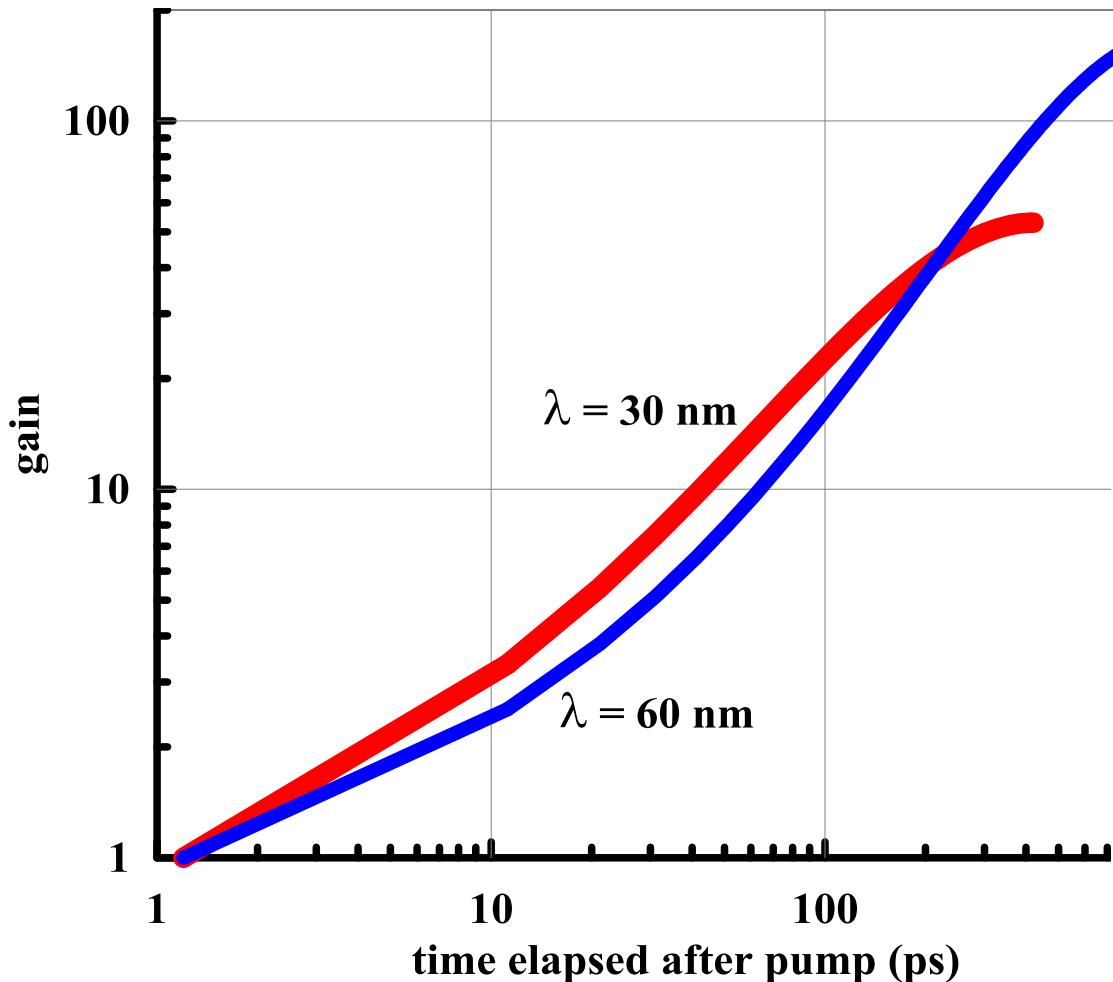

Continuation of the run shown in previous page, here $t=70$ ps.
Absorbed energy F_{abs} is 400 mJ/cm^2 , duration 100 fs . F_{abs} four times overcomes nucleation threshold. Therefore a wide zone I of nucleation (transforming in two-phase mixture) is formed. The thermodynamic states corresponding to this region are located near critical point. 2 is shock in water, 1 is the contact. Compression wave propagates to the right into bulk of Au. Gradually it becomes steeper and steeper and overturns forming weak (p is less than bulk modulus) shock in Au

Deceleration from contact velocity → calculation of linear RTI

$$\gamma = \sqrt{(2k^2\nu)^2 + g k A t - k^3 \sigma / (\rho_A + \rho_w)} - 2k^2\nu.$$

Stratakis et al., Opt.Express, 2009

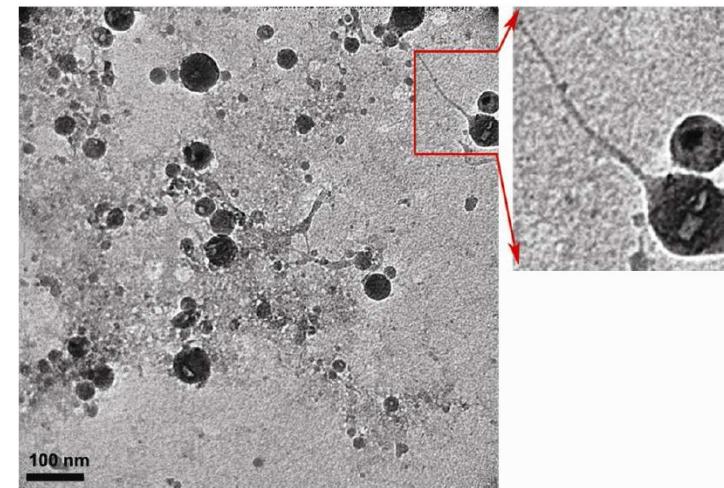

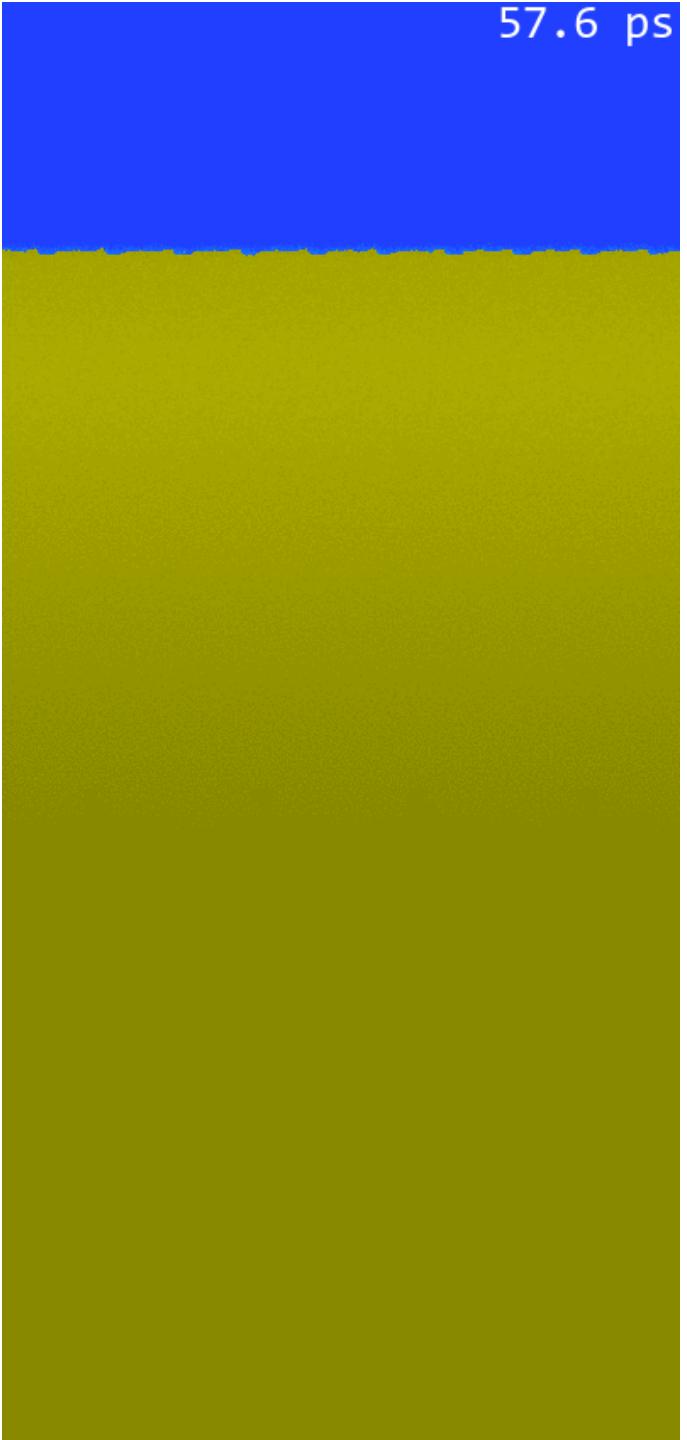

Fig. 2. TEM view of nanoparticles generated via ablation of a bulk Al target in ethanol using laser radiation.

Viscosity of molten gold, surface tension of molten gold

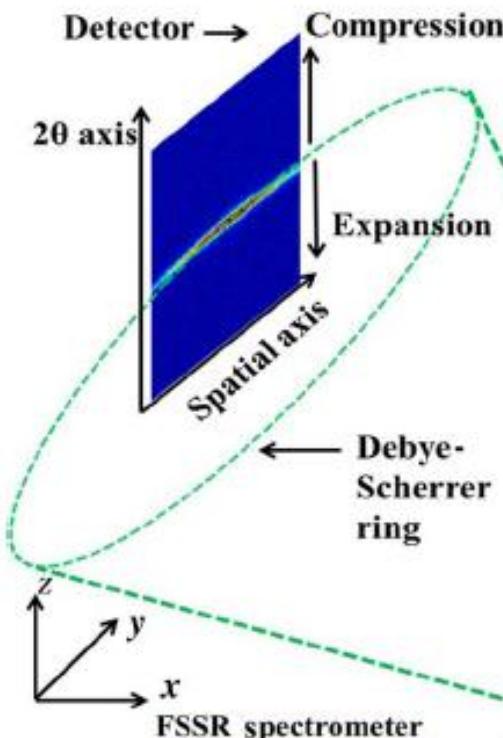

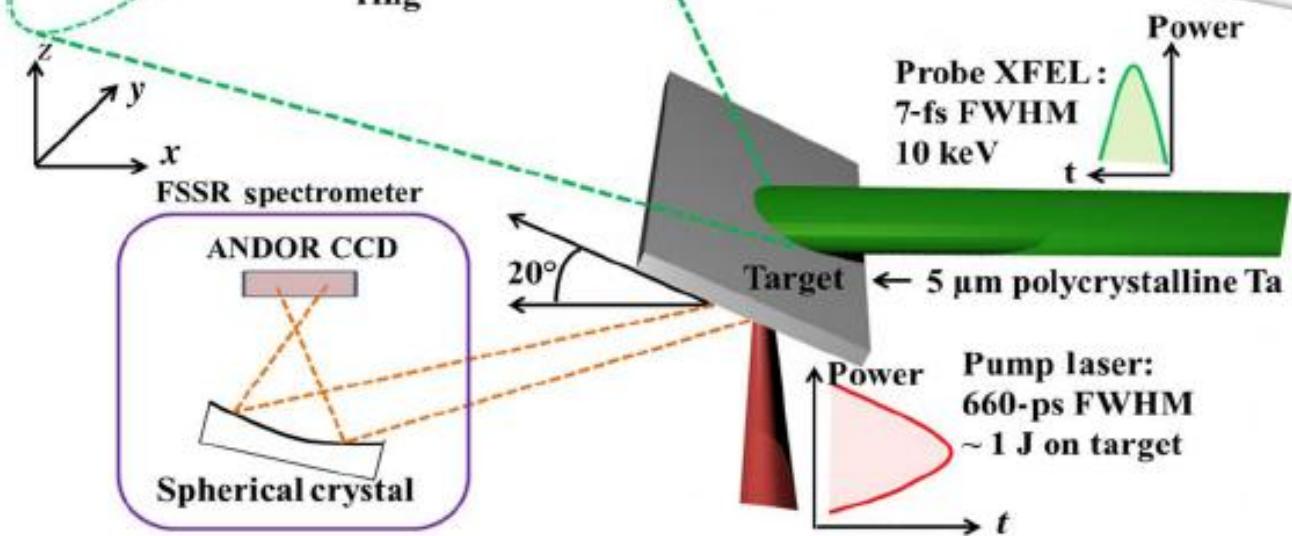

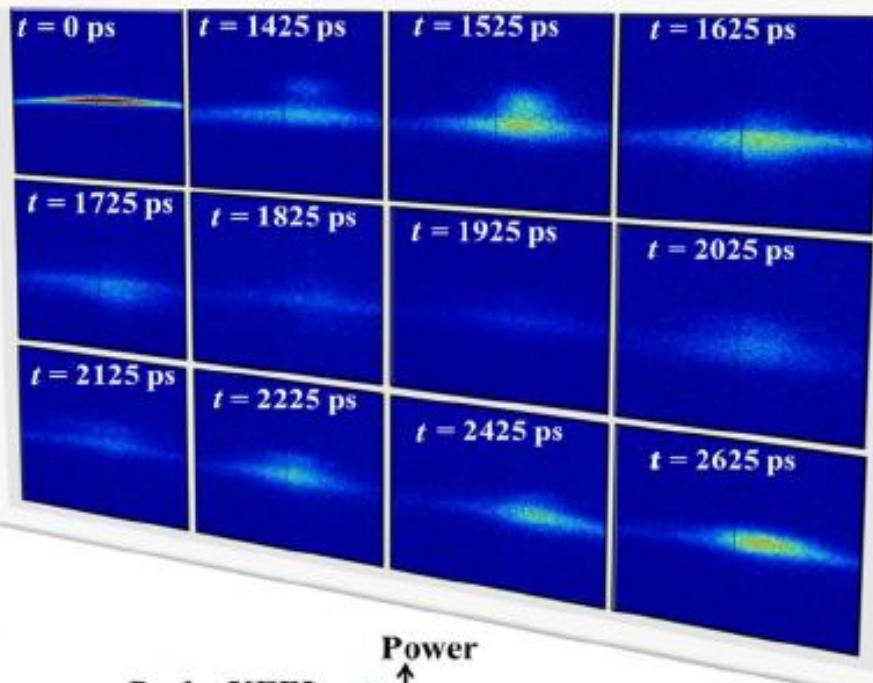

57.6 ps

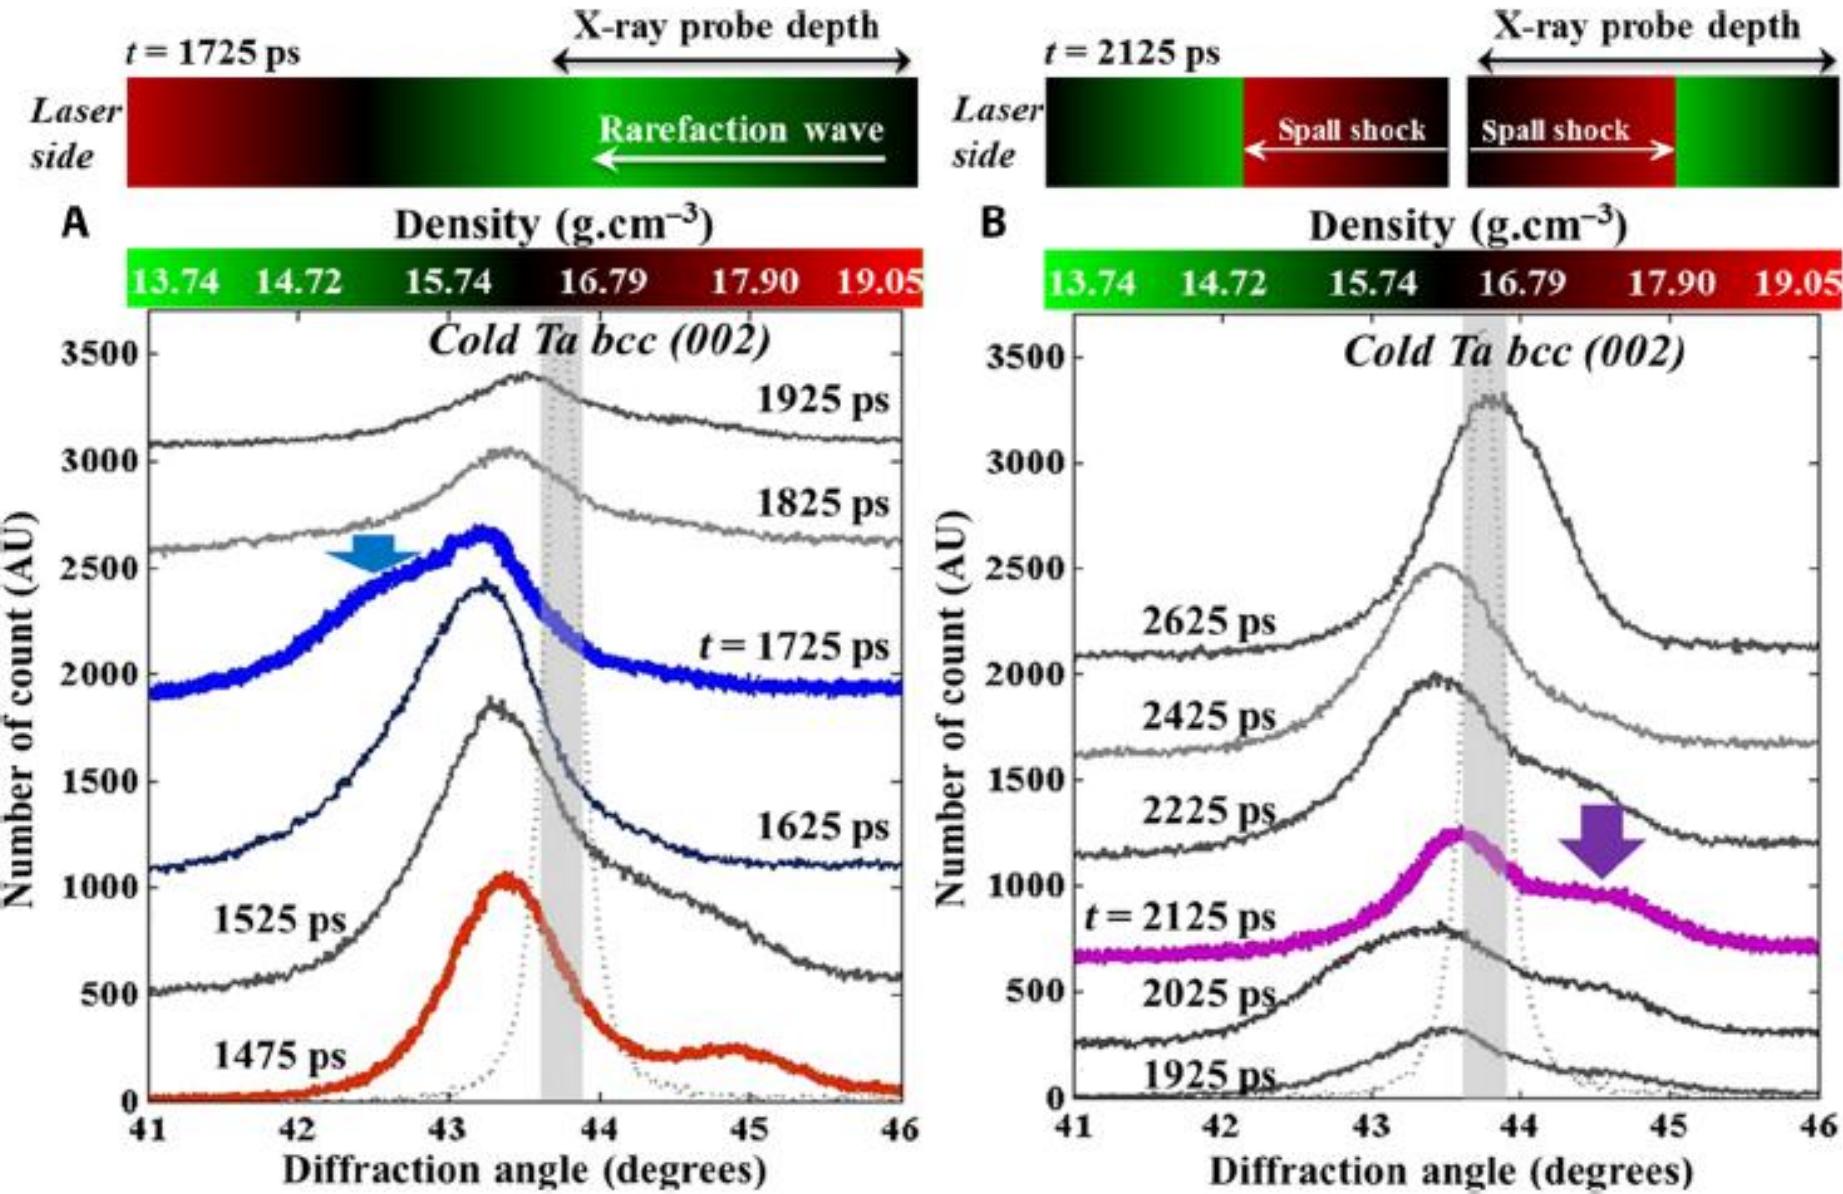

The key phenomena are:
gold (Au, yellow) is irradiated
from above through blue water.
Hot Au expands into H₂O.
Irradiation causes (1) nucleation
and foaming in Au, (2) the layer of
Au (= atmosphere) decelerated by
H₂O appears. Under H₂O
pressure the cavities in a foam
collapse.
(3) there is “accretion” of foam
onto atmosphere.
(4) deceleration of atmosphere
leads to Rayleigh-Taylor instability

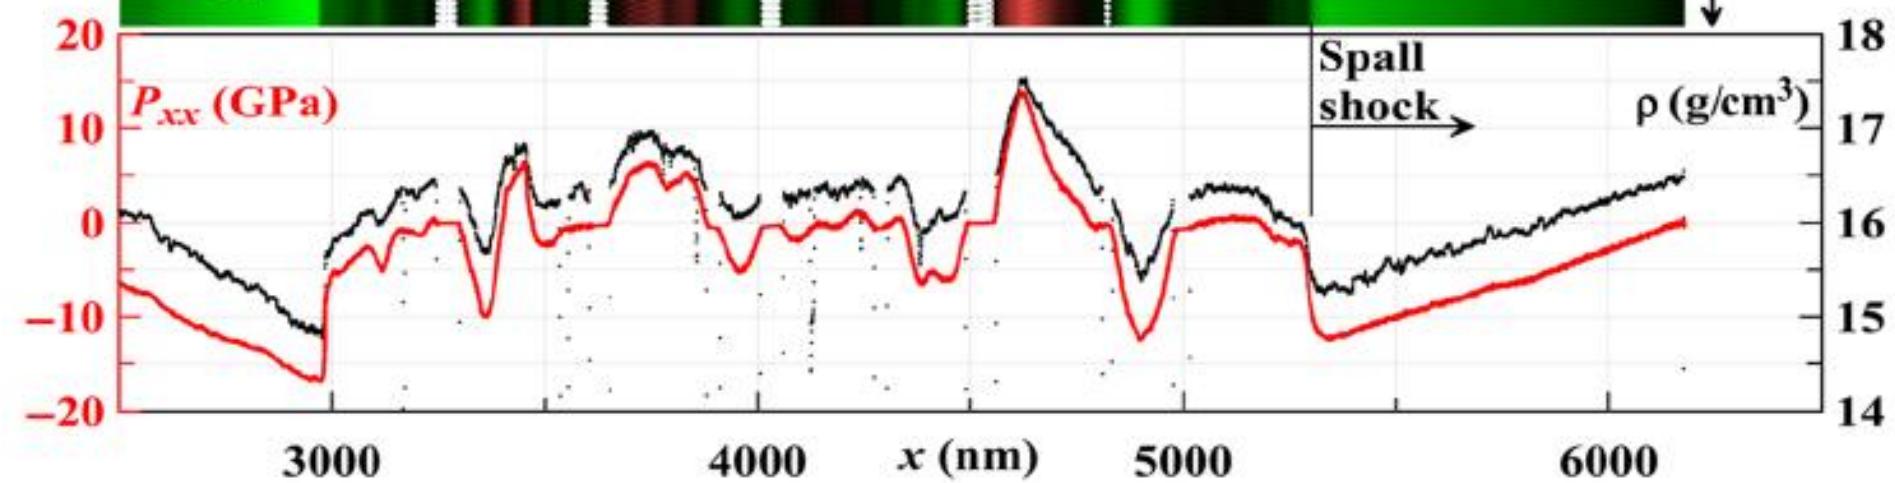

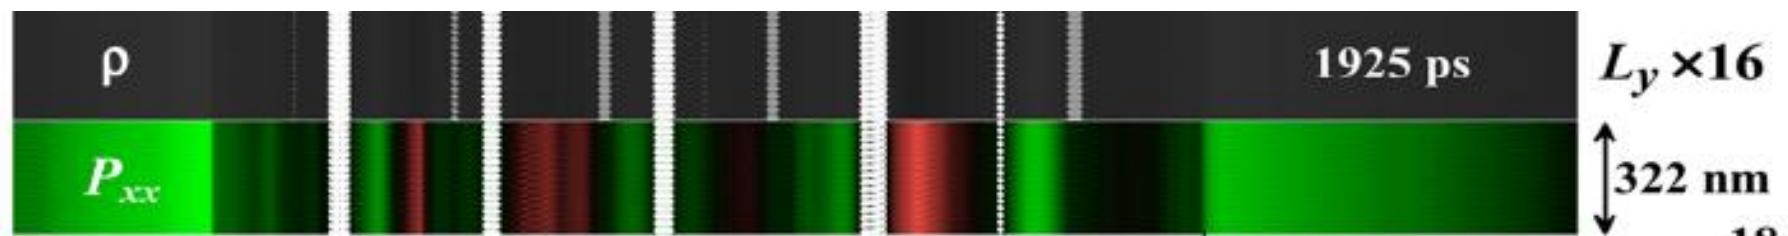

Dynamic fracture of tantalum under extreme tensile stress

- и др.

Conclusions

- Very different laser sources may be used for surface structuring, nanoparticles production, and sintering of powders. They differ in wavelengths, fluences, and durations. Focusing conditions (Gaussian or non-Gaussian beams), diffraction conditions λ/R_L may be varied. Shot rate varies from single shot to many MegaHertz repetition rates.

Conclusions – continuation

- We developed physical models which allows to combine different codes to describe particular situation. These codes are: two-temperature Lagrangian hydrodynamics code; radiation propagation code solving Helmholtz equation; molecular dynamics code together with Monte-Carlo subroutine allowing to include electron heat conduction in metals; SPH code adapted for multiprocessors supercomputers; DFT packages (Elk, VASP etc.) for quantum mechanical simulations
